

Test 1 (Correlation & Data Exploration)

2) Based on the scatterplot I drew I noticed its direction goes down being the higher the Unit Price is, the lower it has quantities sold. Its ~~strength~~ strength is quite close for its pattern, being customers tend to buy ~~more~~ when the unit price is lower, the higher the unit price get, the less customers ~~tend~~ to buy. I think it will have an expected value closer to -1 because each store sells the ~~unit~~ smartphone Accessory at a higher unit price. If that pattern continues customers will tend to buy the accessory less and less since its relationship is the higher the unit price of the accessory, the less customers tend to buy it.

3) Based on what I've noticed, yes, using ~~the~~ Unit Price is a good way to forecast Future Sales Quantity. Because it has a clear pattern being the higher the ~~price~~ unit price, the less it sold. Price and Quantity has a strong relationship because Quantity Sold is always determined by how much is the unit price.

Test 11 (Model Parameters & Fitness)

- 1.) a) the intercept value provided is $\text{Quantity Sold} = 1200 - 0.55(\text{Price})$.
Knowing this value, if the price was set to zero the theoretical quantity will have a higher value because the unit price is already zero, meaning the accessory can already be considered "Free". ~~since~~ Now that it's considered free, more customers will tend to it. no!
- b) the slope value provided is $\text{Quantity Sold} = 1200 - 0.55(\text{Price})$.
With this value its impact to the forecasted Quantity Sold for every additional ~~Peso~~ added to the price is influential since Price and Quantity has a good relationship being the higher the price gets, the lower Quantity gets. no!
- 2.) Returning an R^2 value of 0.48 means its near zero meaning the result of the model is not good. We want to achieve a near to one result ~~than~~ to have a better result for the dataset.
- 3) a real-world predictive model can never achieve zero error because for that model to exist, the model will have to be overly ~~sens~~ sensitive to any noise in the dataset and to achieve that you will have to create a model to recognize that and by then the outputs the model will give will be less accurate.
